## Abstract

**QueryForge – SQL Query Processing System** is a database management system-based application developed to provide an interactive and practical understanding of how SQL queries are processed and executed. The system allows users to enter SQL queries and processes them through various stages, including query parsing, syntax validation, query analysis, optimization, and execution. It identifies errors in queries and provides appropriate feedback to help users understand and correct them.

The proposed system demonstrates the fundamental concepts involved in SQL query processing, such as relational operations, query execution, database interaction, and query optimization. QueryForge can analyze a given SQL query and determine the appropriate sequence of operations required to obtain the desired result. By incorporating query optimization techniques, the system aims to reduce unnecessary operations and improve the efficiency of query execution.

The application provides an easy-to-use interface where users can submit queries and view their execution results. It can also help visualize or represent the different stages through which a query passes before producing the final output. This makes the system useful for understanding concepts that are normally handled internally by database management systems and are difficult to observe directly.

The main objective of QueryForge is to bridge the gap between theoretical database concepts and their practical implementation. It provides students and learners with a platform to experiment with SQL queries, understand query processing mechanisms, identify syntax and logical errors, and gain insights into query optimization. Overall, the project demonstrates how SQL queries are transformed and processed to efficiently retrieve information from a database.
